Job Market Paper In an increasingly migratory, aging, and urbanized world, this study highlights the importance of migration history - even in childhood - to study migration and fertility. The results are relevant for policies that use population size and age distributions to budget for policy services; as well as the understanding of the relationship between female labor market participation with fertility and migration. This article examines the relationship between migration and fertility decisions using the Mexican Family Life Survey. To mitigate concerns about endogeneity, I focus on migration before the age of 12; this is a household rather than individual decision, which limits concerns about the simultaneity of migration and fertility decisions. Additionally, there is little risk of reverse causality because of the time lag between childhood migration and the start of parity; controlling additionally for parental characteristics that may influence migration and later fertility. I find women who migrated in childhood are more likely to have children, and conditional on having children, have more children. Furthermore, women who migrated from rural to urban areas have fewer children than rural-born non-migrants and migrants who move within rural areas. Possible mechanisms include higher education level and less likelihood of marriage upon arrival to urban areas, and more willingness to adapt to labor market opportunities exemplified by more willingness to migrate as adults. Findings suggest that, as migration to cities increases, fertility rates are likely to fall.
